

Precision O-Rings

Back-up Rings

Quad-Rings

Cord-Rings

WHAT EVER THE INDUSTRY
WE HAVE A PART IN IT

Introduction

Welcome to our 9th Edition O -Ring Handbook, we are proud to say that this handbook has become a very popular and useful technical source of information.

Our Range of standard and non-standard sizes is always increasing along with the choice of special compounds to meet every industrial application. On pages 17 to 42 is an example of the most popular sizes available. The O-Ring is now without question the worlds most versatile seal due to its simple shape, low space requirement and its availability in a vast selection of sizes and compounds to meet every requirement.

This handbook is intended as a guide to assist in the selection of O-Rings in both Dynamic and Static applications, along with the choice of the correct compound for a given application. Recommendations are given for groove dimensions, installation procedures, sealing against vacuum, the use of Back-Up rings and Quad rings as an alternative to an O-Ring in certain applications.

We hope you will find our handbook of interest and assistance for your next sealing application, should you require further copies please do not hesitate to contact us.

Dynamic application

Static application (no flanges)

A

Sealing the reciprocating piston of a hydraulic cylinder or a valve in a housing. The O-Ring is mounted in a rectangular groove on the outside of the piston or the valve. The depth of the groove should be such that the O-Ring shows a little above the groove. When the piston is installed in the cylinder, the O-Ring will be compressed by 10-15%, so that an effective amount of sealing capacity will be obtained. The sealing is based on the elasticity of the rubber. Constructional data is given on page 4.

B

Sealing rotating shafts and reciprocating piston rods of a hydraulic cylinder or the spindle of a tap or valve. The O-Ring should be installed in a groove in the body, the depth of the groove should be such that the O-Ring projects a little above the groove. When the shaft or the rod is mounted, the O-Ring will be compressed by 10-15%, so that an effective amount of sealing will be obtained.

C

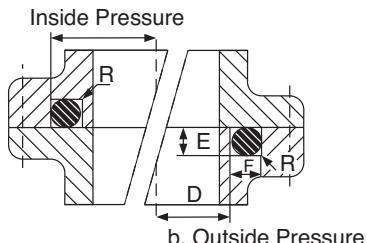

The application of O-Rings for sealing rotating parts is not always advisable. If it is necessary to use a compact sealing element, we recommend the application of a Quad-Ring or other suitable sealing element from our standard programme.

D

It is always advisable to select rings with the largest cross section available. The seal can then withstand higher pressures and will also be safe when the pressure load is subject to variations, particularly when the construction is also subjected to expanding and shrinking movements. The diametric compression of the O-Ring when used statically is approximately 15-20%.

Constructional data is given on page 4.

Static seals (flanges)

E

Flange sealing requires special groove dimensions. This construction provides an excellent seal against fluids and gases under low or high pressures, even when the pipes are subject to vibration. Constructional data is given on page 5. The dimensions must be such that when the O-Ring is exposed to internal pressure, its circumference is positioned close to the outer wall. In the case of external pressure the O-Ring must be positioned close to the inner circumference.

Construction data

We give the following supplementary information:

1. Guide for the choice of an O-Ring for dynamic parts.
2. Guide for the choice of an O-Ring for static parts.
3. Choice of running surface material, finish of running surface and groove, fits and lubrication.
4. Installation instructions.
5. Hardness to pressure ratio.
6. Application of back-up rings.
7. Groove dimensions for both dynamic and static parts and for PTFE O-Rings.
8. Recommendations for use of standard compounds.
9. Resistance properties of various elastomers.
10. Temperature requirements.

1. Guide for the choice of an O-Ring for dynamic parts

The optimum cross section can be obtained from the following table:

Cross Section	Rod Cylinder Diameter
$\geq 1.6 \text{ mm}$	0 - 13 mm
$\geq 2.4 \text{ mm}$	13 - 25 mm
$\geq 3.5 \text{ mm}$	25 - 40 mm
$\geq 5.3 \text{ mm}$	40 - 115 mm
$\geq 7.0 \text{ mm}$	>115mm

Rubber behaves like water and can consequently not be compressed. Its volume will remain unchanged. When O-Rings tend to rotate with the shaft, the rubber may become subject to "winding". When applied to a piston, the ring may twist. It is advisable, therefore, to observe the following rules:

When the outer circumference is exposed to friction:

Outside O-Ring diameter = (0,95 mm to 1,0 mm) x cylinder dia (= A).

The diameter of the groove = cylinder dia (= A) - 2 x groove depth (= E).

The groove depth is shown in the table on page 10.

When the inside circumference is exposed to friction:

Inside O-Ring dia = (0,95 mm to 1,0 mm) x rod dia (= B).

The diameter of the groove - rod dia (= B) + 2 x groove depth (= E).

The groove depth is shown in the table on page 10.

2. Guide for the choice of an O-Ring for static parts

Although in principle any cross section is suitable, it is advisable to take O-Rings with the largest cross section available. The rings can then also be safely used for higher pressures and for varying pressure loads. A distinction must be made between flanges and other static parts.

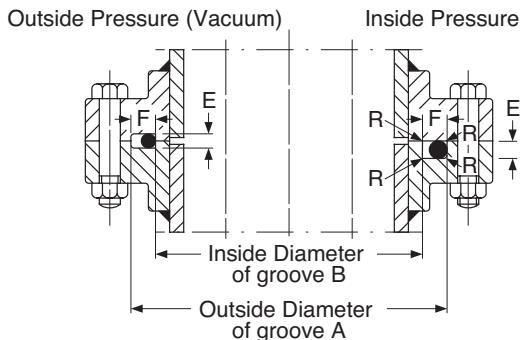

For flanged seals the following rules are applicable:

Pressure from the inside:

A=outside ring diameter (= inside dia + 2 x cross section), so that the O-Ring fits properly on the outside and has some clearance towards the inside.

Pressure from the outside (vacuum): B should be the inside ring diameter, so that the ring fits properly on the inside and has some clearance towards the outside.

For groove dimensions see table on page 10.

Other Static Parts

As far as other static parts are concerned, the same directions as indicated in the case of dynamic parts apply. The O-Ring may be expanded 0-5%, but should be as tight a fit as possible in the groove. The groove dimensions are shown in the table on page 10.

3. Choice of running surface material, running surface and groove finishes, fits and lubrication

The choice of running surface material

In order to obtain the maximum service life for O-Rings sealing dynamic parts, it is recommended to use polished hard steel shafts and rods and honed steel or cast iron cylinder walls.

Honing makes the best surface. Hardened steel causes the least friction, whereas chrome hardening causes considerable friction. Soft materials like aluminium alloys, copper, brass, monel or soft stainless steel are not advisable because their wear resistance is small. The initial friction of elastomers is high; the rubber tends to adhere to the grooves in the surface of the material. The use of harder compounds can reduce this initial friction, but when a very low initial friction is required, Eriflon seals are better suited. Further details on request.

Running surface finish and fits

A close fit between the dynamic parts and a superior surface finish of the sliding parts is of special importance to the proper sealing and long service life of O-Rings.

The sealing clearance

With regard to the allowable clearance values, the table below specifies the I.S.A. fits to be aimed at, dependent on the nominal diameters.

The roughness of the parts sliding against the rubber should be between 0.2 and 0.8 m(Ra) 8 - 32 Ru up to 10mm H9/e8. A surface finish finer than 0.15m (6 Ru) should be avoided, as it would be difficult to maintain a lubricating film.

Nomø	Clearance
up to 10mm	H9 / e8
10 to 60mm	H8 / e9
> 60mm	H7 / f7

The allowable sealing clearance depends on the pressure to be sealed and the hardness of the O-Ring compound used. At elevated pressures a part of the O-Ring will be forced into the sealing clearance. Particularly soft rubber types can be damaged severely. Dependent on the pressures to be sealed, the amount of sealing clearance is bound to maximum values.

Lubricants

For dynamic and pneumatic applications it is essential that the O-Ring should be located with the assistance of a lubricant to prolong service life and prevent initial wear. This is particularly important when installed in components which may not be activated for an indefinite period following assembly.

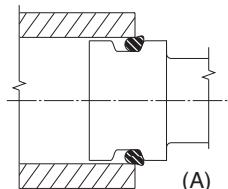

See page 59 for details.

4. Installation instructions

Bevelled edges

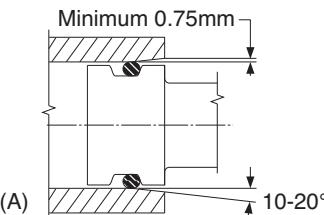

When designing O-Ring sealing devices it is of vital importance that bevelled edges are provided in order that the O-Ring will not be damaged when being installed. In many cases a simple rounding of sharp edges is insufficient. The following illustrations show why this is the case.

CYLINDERS

(A)

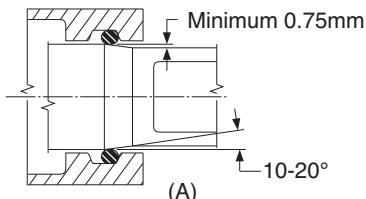

The ring will become wedged and subsequently destroyed because the edges have not been bevelled.

(A)

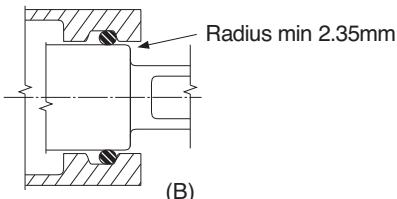

Correctly bevelled edges ensure simple, trouble-free mounting of rings

PISTON RODS & PLUNGERS

(A)

In the case of piston rods and plungers the above construction is preferable.

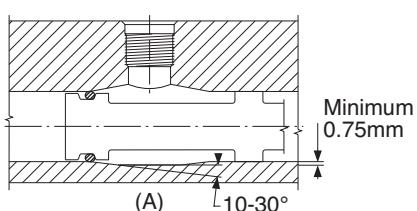

(B)

This construction is deemed satisfactory, but not preferable.

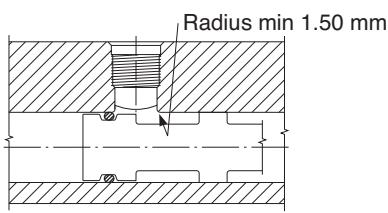

VALVES

When O-Rings must pass a hole while in the process of being installed, care should be taken in order that the rings are not pinched off or lost.

(A)

This construction is preferred

(B)

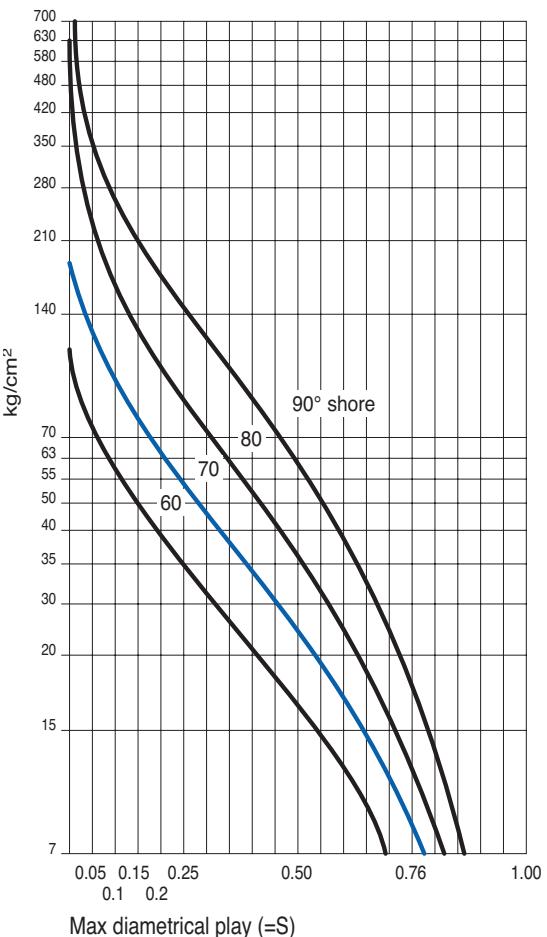

This construction is also workable

When a certain amount of passage is required, we suggest several small diameter holes are made as opposed to fewer larger holes.

5. Hardness to pressure ratio

The diagram opposite gives a guide to the connection between hardness, pressure and clearance.

At pressures over 85 kg/cm², it is always advisable to support the O-Ring by a back-up ring.

The table below specifies the allowable values at the pressures and O-Ring hardness stated for cross sections according to BS1806 and AS 568A. Dimensions in millimetres.

HARDNESS 70-80 ° SHORE A					
Cross section O-Ring "W"					
	1.78	2.62	3.53	5.33	7.00
Pressure	Clearance				
35 bar	0.20	0.25	0.30	0.36	0.41
70 bar	0.15	0.18	0.23	0.25	0.30
100 bar	0.10	0.13	0.15	0.18	0.20
150 bar	0.05	0.08	0.10	0.10	0.11
175 bar	0.03	0.04	0.05	0.06	0.06

HARDNESS 90 ° SHORE A					
Cross section O-Ring "W"					
	1.78	2.62	3.53	5.33	7.00
Pressure	Clearance				
35 bar	0.36	0.41	0.46	0.51	0.51
70 bar	0.30	0.36	0.41	0.46	0.46
100 bar	0.25	0.30	0.36	0.38	0.41
150 bar	0.20	0.23	0.25	0.30	0.30
175 bar	0.15	0.18	0.20	0.25	0.25
200 bar	0.16	0.15	0.18	0.20	0.20
350 bar	0.08	0.10	0.13	0.15	0.15

6. The application of back-up rings

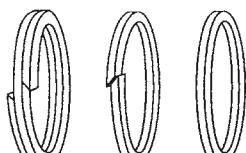

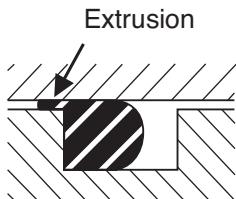

Fig 1 Fig 2 Fig 3

When pressures exceed 85 bar it is advisable (with the exception of flange connections) to install back-up rings that protect the O-Ring from being forced out. They may particularly be needed when hard O-Rings cannot be used or when the tolerances are not close enough to prevent extrusion of the O-Rings. The usual material for back-up rings is PTFE. Other materials are available and can be supplied to special order.

The following types are available:

Fig 1 - Spiral back-up rings

Fig 2 - Split back-up rings

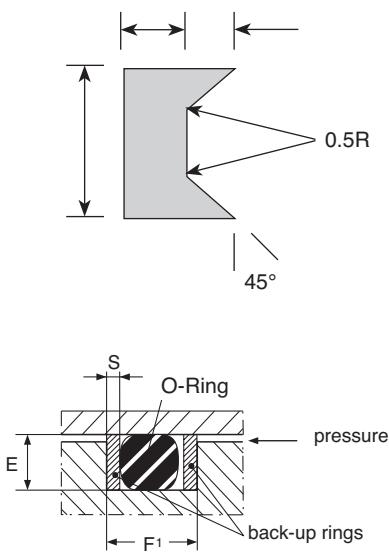

Fig 3 - Solid back-up rings

Spiral back-up rings, Fig 1 are the most popular type, and can be ordered by stating the size of the O-Ring with which they are to be used.

Spiral back-up rings are standard stock items, split and solid back-up rings, Fig 2 and Fig 3, are available to order at short notice.

The width of the back-up ring is identical to the depth of the O-Ring groove; the groove width of the O-Ring is increased by once or twice the thickness of the back-up ring.

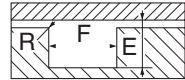

In critical high pressure situations of up to 40 bar the stresses within the O-Ring can rise sharply. In these circumstances we recommend the use of the profiled back-up ring which is specially designed to prevent splitting of the O-Ring at high pressures. These support rings are available in AS/BS standard sizes and are manufactured from a 90° Shore NBR compound.

We stock every size.

Theoretically it is sufficient to install a back-up ring on the side where extrusion can occur only, but in practice back-up rings are often installed on both sides for added protection.

7. Table of groove dimensions for dynamic and static sealing

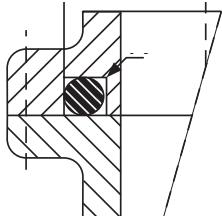

Cross Section	Groove Dimensions								
	Dynamic Application			Static Application				Groove Radius R	
	Depth	Width + 0,10 F - 0,00		Flange Seal		Other Static Parts			
	E +0,00 -0,05	Reciprocating F +0,10 -0,00	Rotary F +0,00 -0,05	Groove Depth E +0,00 -0,05	Groove Width F 0,10	Groove Depth E +0,00 -0,05	Groove Width F 0,10		
1,0 to 1,02	0,81	1,57	1,20	0,68	1,57	0,73	1,30	0,2	
	1,2	1,00	1,80	1,40	0,82	1,80	0,88		
	1,25 to 1,27	1,04	1,85	1,45	0,85	1,85	0,92

	10,0	9,00	13,70	11,20	8,30	13,70	8,50		
	12,0	10,40	16,40	13,40	10,00	16,40	10,20		

Groove dimensions for P.T.F.E. O-Rings

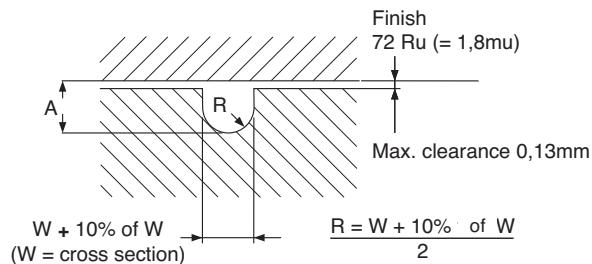

Owing to the less elastic properties of PTFE O-Rings, they should be used for static sealing in axial groove constructions only.

When using PTFE O-Rings in axial grooves or flange constructions, normal groove depths are suitable.

Considering the occurrence of cold flow of PTFE, the best results are achieved if the groove construction stated below is used.

P.T.F.E. O-Rings used in the groove construction as illustrated below are more effective than when installed in normal O-Ring grooves.

$A = W - 10 \text{ to } 20\% \text{ of } W$ (for cross sections 1.78 to 5.33 mm)

$A = W - 10 \text{ to } 15\% \text{ of } W$ (for cross sections 5.33 to 7 mm inclusive)

Compressing P.T.F.E. O-Rings requires higher loads than elastomer O-Rings, consequently P.T.F.E. O-Rings can be used for pressure sealing in axial grooves, not in radial grooves.

In radial grooves P.T.F.E. O-Rings can serve as a pressureless separating seal.

Because P.T.F.E. O-Rings are difficult to expand and difficult to compress, it is advisable to choose dimensions that create a sliding fit.

If P.T.F.E. O-Rings are heated to 80 to 100 °C, they become easier to install.

When the properties of P.T.F.E. are required for chemical or thermal conditions, and higher load pressures to obtain an optimum seal are not possible, we recommend the use of TEFILON-FEP Encapsulated O-Rings as referred to on page 56.

8. Recommendations for use of standard compounds

Recommended media and other data	Shore A ± 5 °	ERIKS Ref. No.	Temp Range °C	ASTM Code '92
Buna N-Nitrile For use with hydraulic and lubricating oils, animal and vegetable oils, acetylene, alcohols, water, air and many other fluids. Good mechanical and physical properties. Compound 36624 is the most commonly used in all industrial applications.	60 70 90	44501 36624 47702	-35 +110	NBR
Ethylene-propylene Chemically resistant; fire resistant to hydraulic fluids, (skydrol, pydraul, lindol, celube 150, phosphate esters), pure aniline, fire extinguisher fluid, mild acids, heated water and steam. Excellent ozone and weathering resistance. Not resistant to mineral oils.	70	55914	-55 +150	EPDM
Chloroprene-NEOPRENE® Resistant to ozone and sunlight. Moderate resistance to petroleum based oils.	70	32906	-45 +100	CR
Fluorocarbon-VITON® Superior quality compound resistant to high temperatures, synthetic and hydraulic fluids and a wide range of chemicals, heavy oxidising fluids, many alkalis, acids and hot air. Exceptional in vacuum applications when a 100% virgin fluoroelastomer is used. See page 50. <i>This is a Genuine Du Pont Performance Elastomer Compound.</i>	75 90	51414 514320	-15 +204	FKM
Silicone For high temperatures, air, oxygen, heated water etc, alcohols and is also resistant to many chemicals. Good ozone resistance, moderate oil resistance and excellent electrical properties.	50 60 70	714655 714166 714177	-60 +230	VMQ
Fluorosilicone Resistant to most fuels and chemicals, silicone based fluids and silicate esters. Good heat and low temperature flexibility, electrical properties and excellent resistance to ozone and weathering.	60	701966	-60 +230	FVMQ

Recommended media and other data	Shore A ± 5°	ERIKS Ref. No.	Temp Range °C	ASTM Code '92
Polytetrafluoroethylene-PTFE Resistant to virtually all types of chemical attack. Not subject to change on ageing as a result of ozone exposure. Water absorption rate is less than 0.01%.			-120 +260	PTFE
Polyacrylate Outstanding ozone resistance and low temperature flexibility. Resistant to high aniline oils, extreme pressure lubricants and transmission fluids. Not recommended for use with water.	70	3351	-25 +160	ACM
Polyurethane Good abrasion resistance, tear strength and low temperature flexibility. Resistant to oils and fuels at normal ambient temperature.	70	522219	-30 +70	AU
Tetrafluoroethylene-AFLAS® Suitable for use with a wide range of chemicals together with superior ozone resistance. Has good physical properties and high abrasive resilience. Recommended for use with many automotive and aerospace lubricants and is excellent in hot water and steam applications.	80 90		-15 +204	TFE
FEP Encapsulated A seamless FEP encapsulated O-Ring with a Viton® or Silicone core. Extremely high chemical resistance with low vapour permeability and compression set.			-60 +204 +260	FEP PFA
Perfluorelastomer - KALREZ® Superior quality compound for high temperatures and most chemicals. The compound combines chemical properties of Teflon and the mechanical properties of Viton®. Compounds 4079, 1050LF and 6375 are the most commonly used and are readily available. For solvents, ketones, esters, ethers, inorganic and organic acids and lyes, highly oxidizing agents, chlorine and compounds of chlorine, fuels, hydraulic fluids, thermal fluids and steam. Note: Please refer to page 59 for details of KRYTOX® Lubricant.	80 75 75 90 80 85	1050LF 4079 6375 3018 2037 2035	-41 +280 -50 +316 -20 +275 -50 +288 -50 +210 -50 +210	FFKM

9. Resistance properties of various elastomers

We would emphasise that this chart should be used as a guide only. We will be glad to send you our detailed list of chemical resistance properties covering up to 15 elastomers and some 1500 fluids and gases, upon application.

	Buna-N Nitrile	Ethylene Propylene	Neoprene®	Urethane	Silicone	Fluoro-silicone	Fluro- elastomer Viton	Poly-acrylate	Kalrez® Perfluor elastomer	Teflex

10. Temperature Requirements

When considering a choice of compound, both high and low limits as well as operating temperature must be taken into consideration, together with the anticipated time element of each high and low point. The parameters shown in the chart are based on average conditions for a period of approximately one thousand hours. Most base polymers will exceed the recommended temperature guide for short intermittent periods.

Another important point to be considered in very critical conditions is

the fact that rubber when exposed to extended periods of high temperature will expand, and therefore it may be necessary to increase the area of the groove, and in opposing conditions rubber exposed to prolonged periods of low temperature will tend to contract and a reduction of groove size may be desirable or alternatively a higher degree of squeeze should be allowed for on initial design.

Dimensions chart

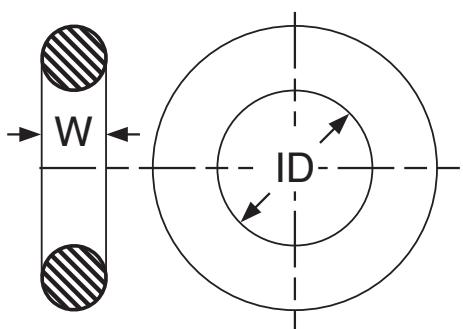

On pages 17 to 42 you will find over 2800 sizes listed in order of their inside diameters, followed by the cross section diameter. The sizes contained in our programme represents over 95% of the international market, and conform to the following world standards:-

American	AS 568A
British	BS 1806 & 4518
French	AFNOR 47501
German	DIN 3770 & DIN 3771
Japanese	JIS 2401 & JAS 06605
Swedish	SMS 1586

Hardness of O-Rings

The hardness of all elastomers is generally expressed in accordance with the internationally accepted scale Shore A.

All figures quoted are subject to a tolerance of +/- 5° and the higher the number the harder the compound. Standard O-Rings are usually available between 60° and 90° with 70° being the standard which will always be supplied in the absence of an alternative being requested.

Ordering

When ordering an O-Ring please state either the size reference number or the internal diameter, followed by the cross section diameter, and then the type of material and shore hardness required. All dimensions are quoted in mm.

Tolerances

O-Rings are manufactured to close tolerances as defined in BS 1806-1989, BS 4518-1982, ISO 3601/1 and DIN 3771/1 up to and including an internal diameter of 670mm and cross section of 7mm.

The tables below relate to O-Rings manufactured from our standard Nitrile compound 36624 and refers to the smaller diameter within the specified range.

With other materials and shore hardness, slight deviations may occur due to the differing shrinkage behaviour of proprietary compounds

Application of O-Rings against Vacuum

When constructing O-Ring grooves for vacuum sealing, it is important that the groove is filled by the O-Ring as much as possible. As a general rule we recommend to aim for 99% volume to void as when any elastomer is exposed to vacuum, it will shrink to a certain extent. This is also important to prevent the O-Ring from sliding or rolling. The surface to be sealed should be machined as smooth as possible but not less than 4RMS.

In the case of high vacuum sealing the gas permeability and the degassing properties of the O-Ring play an important part. These properties vary widely among the various elastomers and are also highly dependent on temperature and the medium handled.

Always avoid any kind of vibration on this type of application.

In the majority of cases Viton® is the preferred compound for sealing against vacuum, but it is essential that this is a 100% virgin fluoroelastomer, as supplied by Du Pont Performance Elastomers, and not a substitute FKM, often referred to as a commercial grade of Viton®, as these have been blended with hydrocarbon elastomers, significantly degrading their resistance to heat, permeation and compression set, rendering them unsuitable for use in a vacuum application.

When the requirements of high vacuum and elevated temperature prevail a Perfluorelastomer may offer the best solution.

Cross Section	Groove Depth	Groove Width		
1.78	1.27	1.32	2.11	2.24
2.62	1.88	1.98	3.00	3.12
3.53	2.57	2.62	3.99	4.14
5.33	3.86	3.94	5.99	6.12
7.00	5.11	5.18	7.75	7.87

The figures above represent the cross section according to BS 1806 and AS 568A for vacuum sealing.

Degassed O-Rings

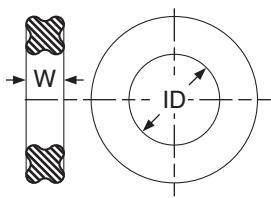

An increasing number of applications including Vacuum Nuclear, Semiconductor, Analytical & Pharmaceutical for example now require Seals to be Degassed prior to use.

This is a process we are able to offer in house at short notice together with our 24 hour express service. Following this procedure we can either bulk pack in sterile uv packaging or individually pack with customers own logo, barcodes, part number and any other relevant information subject to quantity.

The preferred compounds for this procedure are either 100% virgin fluoroelastomer being genuine Viton® and not a substitute FKM and Silicone-VMQ both of which are able to withstand the temperature required for the Degassing process, which is designed to release any volatile materials into a special vacuum enclosure.

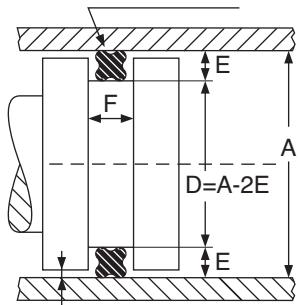

Quad-Rings

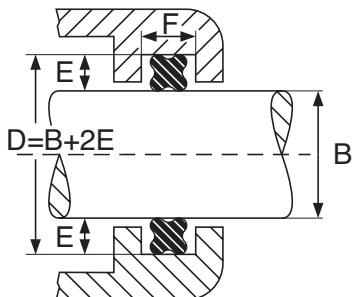

The Quad-Ring is a self-sealing rubber ring with four rounded sealing lobes. Quad-Rings were primarily designed to replace O-Rings in cases where the application of O-Rings is not satisfactory. The four contoured sealing lobes have greater sealing capacities and provide a useful oil groove. The diametrical compression required is lower than if O-Rings are used. Less compression means less friction and consequently less wear in dynamic applications.

The dimensions of Quad-Rings are equal to the dimensions of O-Rings in accordance with AS 568.

When a piston with an O-Ring makes its stroke, one section of the O-Ring will tend to roll with the piston, while the rest of it slides. In many cases the O-Ring will suffer from permanent torsion. The rubber will then begin showing signs of fatigue, so that leakage will occur. Eventually the O-Ring will break. When used for the same application, a Quad-Ring will resist the tendency to roll and twist, due to its relatively square cross section.

Like O-Rings, Quad-Rings are installed in rectangular grooves. Piston and rod seals are instances of dynamic applications. A piston seal is installed on the piston and seals the piston in relation to the cylinder wall. A rod seal seals along the outer circumference of the rod.

The contoured elastic sealing lobes guarantee easy and equal sealing. Quad-Rings are suitable for full vacuum and can be used in dynamic applications up to 100 atm., without back-up rings. In static applications the pressure may be over 100 atm.

The most popular compound is a Buna N-Nitrile which can be used in 90% of all cases and is available from stock in all AS/BS sizes. Viton® is also available from stock in most imperial sizes and EPDM is also available in a limited range of popular sizes.

Quad-Rings for rotating Shafts

Selecting Rings

Selecting the cross section of the rings

The service life of a ring is also dependent on the stroke length, frequency, continuous or intermittent service etc.. Larger rings and larger cross sections will last longer and will accept more play. It is advisable to select the largest cross section available of the ring size required.

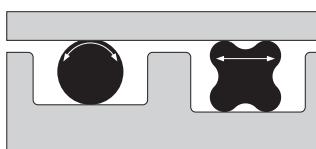

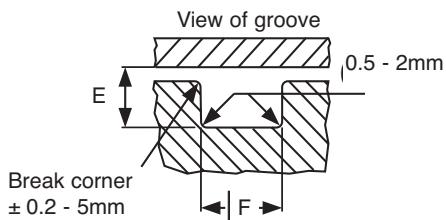

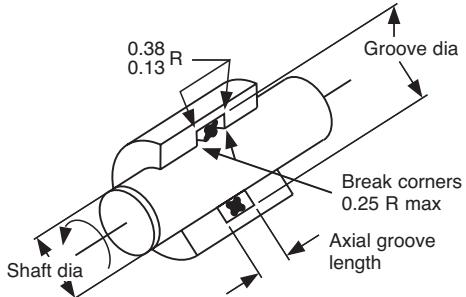

Surface Finish

Friction wear can be reduced to a minimum value by machining the sealing surface as smooth as possible. Recommended is a surface finish of 35 μm or finer, provided the sealing surface remains capable of retaining a lubricating film.

Quad-Ring grooves

As a rule, like O-Rings, Quad-Rings are installed in non-adjustable grooves. The depth of the groove should be such that the Quad-Ring is compressed after installation. The minimum compression required depends on the application. In the case of fast moving seals the compression should not be too high, to avoid too much friction. The groove must be wide enough to accept deformation of the ring, since the volume of the Quad-Ring does not change, consequently the groove must be wider than the Quad-Rings. The possibility of swelling of the rings must be taken into consideration.

The groove should be rectangular, sometimes however, turning the groove is easier if the groove sides are slightly conical. If the bevel is not over 5°, such conical grooves are acceptable.

Diametrical clearance

When exposed to elevated pressures part of the Quad-Ring may be extruded into the clearance and the rings may be damaged to an unacceptable degree.

The amount of diametrical clearance is consequently tied to certain maximum values. The table below shows the admissible maximum clearances for the Quad-Ring sections stated if the hardness of the Quad-Ring material is 70° Shore.

Installation

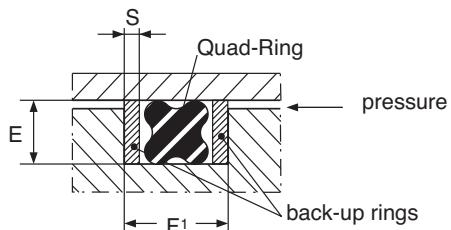

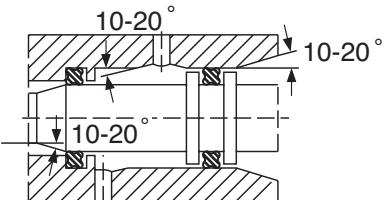

When the Quad-Rings are installed, they must be protected from being damaged. Sharp edges and corners should be rounded, and in the majority of cases shafts, rods, and cylinder ends should be bevelled.

If a Quad-Ring has to pass a hole in the cylinder wall, the sharp edge of this hole should also be bevelled.

Quad-Rings must never be used over threaded ends.

It is always advisable to apply a lubricant when installing Quad-Rings.

For the applications of back-up rings please refer to page 9.

Cord Rings

When the exact size required is not available in a standard moulded O-Ring it is often quite acceptable in a static application to use a Cord Ring. These can be made to any size at very short notice in our own in-house workshop from the extensive range of cords listed.

Standard general purpose cords are normally extruded to Class E2, it follows therefore that Cord Rings produced from this range will have a greater cross section tolerance than that of a moulded O-Ring. The reverse however applies to our Special Purpose cords which are specially extruded to a very tight tolerance which we classify as Class A1 and which are less than those of a moulded O-Ring.

Cord Rings with a 3mm to 12mm cross section are produced with a 45° scarf joint and Cord Rings above a 12mm cross section are produced with a 90° butt joint.

Our Silicone & EPDM cord is manufactured entirely of raw materials which are allowable ingredients under FDA protocols.

Encapsulated O-Rings

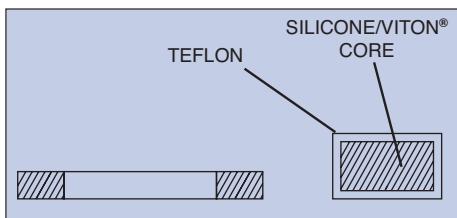

Consisting of a seamless and uniform TEFLON-FEP encapsulation which completely encloses a core material of either Silicone ZZR-765B or Viton® elastomers.

The dimensions of the O-Ring are characterised by the inside diameter and the cross section I.D. x C.S.

The seal with a solid core will provide the best resistance to compression set and also has good recovery characteristics, whilst the seal with a hollow core will provide effective sealing in cases where the amount of force is limited. The seal with a hollow core is also particularly useful in sealing delicate objects such as glass or plastics.

The encapsulated seal can also be supplied in rectangular sections. For these profiles the section diameter must not be less than 2-62mm to provide sufficient elasticity.

Function

The seamless uniform and integral TEFLON-FEP encapsulation of the O-Ring is responsible for the sealing effect, whereas the continuous reset and the constant pressure of the encapsulation on to the sealing point is accomplished by the elastomer core. The result is an overall sealing compression increasing with medium pressure. The encapsulated O-Ring behaves like a highly viscous fluid, any pressure exerted on the seals is transmitted practically undiminished in all directions.

Properties

- 1) High chemical resistance due to the TEFLON-FEP encapsulation .
- 2) Operational temperature range of - 60°C to +204°C.
- 3) Anti-adhesive properties / non stick surface.
- 4) Sterilisable - FDA approved
- 5) Low vapour permeability & minimal water absorption.
- 6) Low compression set.

Remarks

Encapsulated O-Rings are resistant to practically all chemicals due to the TEFLON-FEP encapsulation. The FEP encapsulation is integral and has no weak points such as obvious seams.

- 98% of all technical applications are within the operating temperature range of the O-Ring.
- The TEFLON-FEP encapsulation of the O-Ring has a very low coefficient of friction.
- The elastomer core of the O-Ring ensures a continuous intensive contact with the sealing surface.

Combining the best qualities of TEFLON-FEP resins and Silicone or Viton® elastomers the O-Ring is an inexpensive, efficient and economical solution to many critical sealing problems.

For further information send for separate brochure.

O-Ring Assortment Boxes

A comprehensive range of O-Ring assortment boxes covering all the most popular international sizes. The assortment boxes are a convenient and economical way of keeping a selection of the most popular sizes readily available for an emergency, or as an essential part of the equipment of the maintenance or service engineer. The rigid plastic containers will also provide ideal storage conditions.

Accessories

Circometer

The use of this measuring tape enables the exact circumference of an O-Ring or Gasket to be determined.

Range A	20-300mm
B	300-700mm
C	700-1100mm
D	1100mm-150mm

O-Ring Measuring Gauge

A useful expanding instrument to identify O-Ring sizes from BS001 to BS455.

KRYTOX® - Oil & Grease

A high quality lubricant with unique properties derived from its fluorinated structure of polyhexafluoropropylene oxide, making it a highly lubricious liquid with extremely low volatility, ideal for use in severe environments. Krytox® oil is insoluble in water, acids, base and all other solvents and is non-toxic and completely safe for use in all oxygen services. We recommend it as an O-Ring lubricant in high temperature applications, together with Vacuum, Aerospace, Nuclear, Semiconductor and other demanding applications.

O-Ring Tool Kit

Installing and extracting O-Rings can in some cases be a problem and a time consuming operation. In these situations the specially designed tools are an invaluable asset to the engineer. The tools are fabricated from a corrosion resistant material and may be used in sterile applications.

Use of tool kit

The use of the tools will become familiar to you within a short period of time. However several examples are given as illustrated.

Piercing tool

Use this tool to remove small O-Rings in difficult locations, where damage of the O-Ring is of no consequence. (Fig 1)

Pointed prying tool

Use to remove O-Rings in difficult locations by prying from the bottom of the groove. Insert as shown (Fig 2), rotate and move handle toward the wall. (Fig 3)

Flat face prying tool

Use to remove O-Rings from grooves as shown (Fig 4). To install in the groove, pull upward until the O-Ring snaps in place. (Fig 5)

Jogging and removal tool

To install O-Rings in their grooves, push the ring past the groove (Fig 6). Use the heel of the tool to push a section of the O-Ring into the groove (Fig 7), then use the tip to pull the entire O-Ring into position. (Fig 8)

Prodding tool

Use to remove O-Rings in cases where the groove is close to the surface (Fig 9). This tool will also be helpful to seat the O-Ring in the groove (Fig 10) as well as applying lubricant to an O-Ring that is already in position.

Tweezers

Use to hold the O-Ring for dipping into a lubricant, as well as for holding the O-Ring in position when fitting into difficult applications.
